

Triple only	<b>P12 Magnetism and the Motor effect / P13 Electromagnetic Induction</b>
	Kettering Science Academy

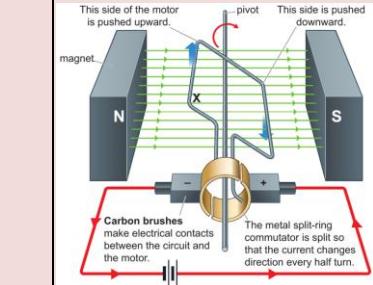

<b>P12a Magnets and magnetic fields</b>	
<b>Magnet</b>	An object that has its own magnetic field around it.
<b>Permanent magnet</b>	A magnet that is always magnetic such as a bar magnet.
<b>Temporary magnet</b>	A magnet that is not always magnetic, such as an electromagnet or an induced magnet.
<b>Induced magnet</b>	A piece of magnetic material that becomes a magnet because it is in the magnetic field of another magnet.
<b>Uses of magnets</b>	Motors, loud speakers, generators, door locks, knife holders.
<b>Magnetic field</b>	The area of magnetic force around a magnet where it can affect magnetic materials or induce a current.
<b>Magnetic field lines</b>	Magnetic field lines are a visual tool used to represent magnetic fields.
<b>Bar magnet field shape</b>	
<b>Uniform magnetic field shape</b>	
<b>Magnetic field direction</b>	From North to South.

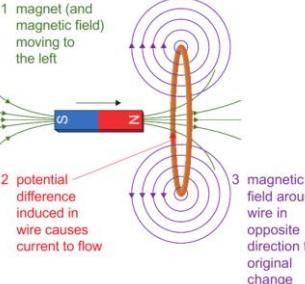

<b>Earth's magnetic field</b>	The North Pole is a magnetic south pole (because it attracts the north of bar magnet).
<b>Magnetic materials</b>	A material, such as iron, steel, nickel and cobalt that is attracted to a magnet.
<b>Plotting compass</b>	A small compass used to find the shape of a magnetic field.

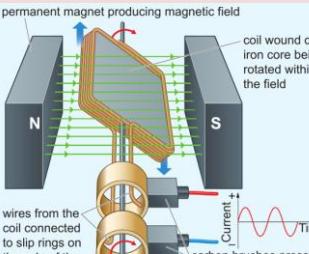

<b>P12b Electromagnetism</b>	
<b>Electromagnetism</b>	Is the study of the electromagnetic force.
<b>Magnetic effect</b>	A current flowing through a wire causes a magnetic field.
<b>Wire magnetic field shape direction (right hand rule)</b>	
<b>Wire magnetic field strength</b>	Stronger nearer the wire and with higher current.
<b>Solenoid</b>	A coil of wire with current running through it. 
<b>Electromagnet</b>	A magnet made using a coil of wire with electricity flowing through it.
<b>Solenoid magnetic field shape</b>	
<b>Solenoid magnetic field direction</b>	From north (negative side) to south (positive side).
<b>Stronger magnetic field of a solenoid</b>	The magnetic field of a solenoid can be made stronger by putting a piece of iron (an iron core) inside the coil or increasing the current.

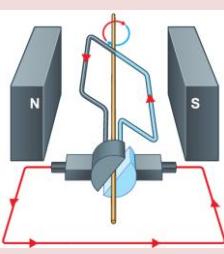

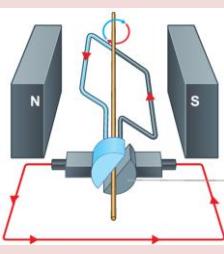

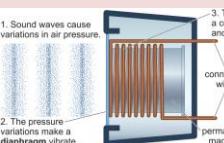

<b>Higher only P12c Magnetic forces</b>	
<b>Motor effect</b>	The force experienced by a wire carrying a current that is placed in a magnetic field.
<b>Two magnetic fields interaction</b>	 <p>When the wire carrying a current is put between the magnets, the two fields interact to produce a force.</p>
<b>Direction of force from motor effect</b>	Fleming's left-hand rule – index finger points in direction of magnetic field, middle finger points from + to - current, thumb points in direction of force. 
<b>Force from motor effect is greatest when...</b>	Magnetic field and electric field are at right angles, wire is longer, current is greater, magnet is stronger.
<b>Magnetic flux density, B</b>	The strength of a magnetic field.
<b>Newtons per amp metre (N / A m)</b>	Units of magnetic flux density.
<b>Tesla, T</b>	Same as newtons per amp metre.

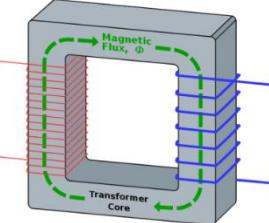

<b>Calculating forces from the motor effect</b>	Force = Magnetic flux density x current x Length $F = B \times I \times L$ 
	Force (F) = newton (N) Magnetic flux density (B) = tesla (T) Current (I) = amp (A) Length (L) = metre (m)

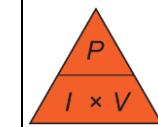

<b>Electric motor</b>	An electric motor is an electrical machine that converts electrical energy into mechanical energy. 
<b>Split-ring commutator</b>	The commutator ensures that the current is always flowing in the correct direction to make the coil continue to spin.

<b>Higher only P13a Electromagnetic induction</b>	
<b>Induced voltage (current) in a loop of wire</b>	

<b>Electromagnetic induction</b>	A process that creates a current in a wire when the wire is moved relative to a magnetic field, or when the magnetic field around it changes.
<b>Induce</b>	To create. For example, a wire in a changing magnetic field has a current induced in it.
<b>Factors affecting the potential difference induced in a transformer</b>	- the number of turns in a coil of wire - how fast the magnetic field changes or moves past the coil
<b>Generators</b>	Generator is a dynamo alternator or similar machine for converting mechanical energy into electricity.
<b>Alternator</b>	A machine for converting mechanical energy into electrical energy (alternating current).
<b>Alternator – how it works</b>	The coil of wire rotates inside a magnetic field. As the coil turns, a voltage is induced in the wire. The ends of the coil are connected to slip rings.    The commutator swaps the connections every half-turn so the current in the external circuit always flows in the same direction.  Current vs Time graph: A sinusoidal wave representing alternating current over time.
<b>Slip rings</b>	A ring in a dynamo or electric motor which is attached to and rotates with the shaft, passing an electric current to a circuit via a fixed carbon brush pressing against it.
<b>Carbon brushes</b>	A small block of carbon used to carry current between the stationary and moving parts of an electric generator or motor.

<b>Dynamo</b>	A machine for converting mechanical energy into electrical energy (direct current).
<b>Dynamo – how it works</b>	The coil of wire rotates inside a magnetic field. As the coil turns, a voltage is induced in the wire. The ends of the coil are connected to commutator.      The commutator swaps the connections every half-turn so the current in the external circuit always flows in the same direction.  Current vs Time graph: A sinusoidal wave representing alternating current over time.
<b>Microphones</b>	Microphones convert the pressure variations in sound waves into variations in current in electrical circuits.  
<b>Loudspeakers</b>	Loudspeakers convert variations in an electrical current into sound waves.

<b>P13b The National grid</b>	
<b>National grid</b>	The system of cables and transformers that transfers electricity from power stations to homes and businesses.
<b>Transmission lines</b>	The wires (overhead or underground) that take electricity from power stations to towns and cities.
<b>Voltage in the national grid</b>	Power station = 25 kV Overhead cables = 400 kV Factories = 33 kV Homes = 230 V
<b>Transformer</b>	A device that can change the voltage of an electricity supply.
<b>Step-up transformer</b>	Increase voltage and decreases current.
<b>Step-down transformer</b>	Decrease voltage and increases current.
<b>Transformer structure</b>	
<b>Coils</b>	Primary coil electricity in, secondary coil electricity out.
<b>Higher only</b>	
<b>Transformers and current</b>	Transformers only work with alternating current.
<b>Alternating current</b>	Current whose direction changes many times each second.
<b>How transformers work</b>	Current passing through the primary coil induces a current in the secondary coil of higher voltage and lower current (or vice versa).

<b>Voltage across the coils calculations</b>	<p><math>\frac{V_p}{V_s} = \frac{N_p}{N_s}</math></p> <p><math>N</math> – number of turns in the coil  <math>N_p</math> – primary coil  <math>N_s</math> – secondary coil  <math>V_p</math> – voltage primary coil  <math>V_s</math> – voltage secondary coil</p>
<b>P13b Transformers and energy</b>	
<b>Potential difference or voltage</b>	Is a measure of the energy transferred by each coulomb of charge that flows through a wire.
<b>Electrical power</b>	The amount (rate) of energy transferred per second. The units are watts (W).  Electrical power = Current x Voltage  $P = I \times V$  
	Power (P) = watt (W) Current (I) = amp (A) Voltage (V) = volt (V)
<b>Conservation of energy in transformers</b>	If the voltage increases, the current decreases, so energy is conserved since: Power = current x voltage
<b>Conservation of energy in transformers</b>	The power supplied to a transformer in the primary coil must be equal to the power transferred away from the secondary coil.

<b>Transformer calculations</b>	Primary coil voltage x primary coil current = secondary coil voltage x secondary coil current $V_p \times I_p = V_s \times I_s$ Voltage (V) = volt (V) Current (I) = amp (A)
<b>Primary coil voltage vs Secondary coil voltage</b>	The potential difference (voltage) is greater in the primary coil if it has more turns than the secondary coil.
<b>Higher only</b>	
<b>Power calculations</b>	power (W) = $\frac{\text{energy transferred (J)}}{\text{time taken (s)}}, P = \frac{E}{t}$ electrical power (W) = current (A) x potential difference (V) electrical power (W) = current squared (A) <sup>2</sup> x resistor (Ω)
